Abstract

The present survey deals with the floristic study of Dalab Woodlands, located in Manesht and Ghelarang protected area, western Iran. It covers an area of 4335 ha. In total, 224 vascular plant species belonging to 46 families and 156 genera were identified. The largest families are Asteraceae (29 species), Fabaceae (23 species), Poaceae (22 species), and Apiaceae (18 species). *Astragalus* (13 species), *Centaurea* (9 species), *Onosma* (6 species), *Bromus* (5 species) and *Amygdalus* (3 species) are the most diverse genera of the region. The life form spectrum includes: hemicryptophytes (36.6 %), therophytes (33 %), cryptophytes (13.8 %), chamaephytes (8.9 %) and phanerophytes (7.6 %). From the chorological point of view, the largest proportion of the flora belongs to the Irano-Turanian (68.7 %) elements. About 22.32 % of the Dalab Woodlands species are endemic to Iran and six rare species including *Alrawia bellii*, *Arum giganteum*, *Cousinia cylindracea*, *Echinops kotschy*, *Thymbra spicata* and *Zeugandra iranica* are also identified in this region.

Keywords: Flora; plant species; life form; Dalab woodlands; Ilam

1. Introduction

Zagros forests cover a vast area of the Zagros Mountain ranges (ca. 5 million hectares), about 40 % of Iran's forests [1-3]. Geographically this important natural ecosystem has been divided into three parts: northern, central and southern Zagros [4]. The central Zagros (including Ilam, Lorestan, and Kermanshah and Hamadan provinces) is globally significant for protection of ecosystems, species and genetic biodiversity. Extreme relief and climatic conditions have led to a great diversity of ecosystems and habitats over small geographical areas. In turn, this has created a home for a vast range of plant and animal species, especially several endemic and endangered species [5]. Unfortunately the entire Zagros forest and its vulnerable ecosystem is degraded by various factors, especially overexploitation caused by poverty, shortage of regional development opportunities, low literacy rate and high dependence of residents on forest resources for daily life.

Floristic survey of an area is an essential tool for identifying the floristic composition, particularly endemic, resistant and endangered species [6]. Gathering the knowledge is the first step toward

determining the potential and production potential of a region, increasing the density of vegetation [7], managing ecosystems for long term viability and sustainability, and preventing the destruction of habitats [8-15]. The present study aimed to identify the floristic composition, life forms, and chorology of Dalab Woodlands flora (North East of Ilam Province, Iran). The result provides an overview of biodiversity among vascular plants of western Iran with special emphasis to flora, life-forms and chorology.

2. Material and methods

Dalab forested region, with a 4335 ha area is located in Manesht and Ghelarang protected area, northeast of Ilam province, in the west of Iran. This region is situated between 46° 20' 56" and 46° 27' 37" East longitude and 33° 40' 20" to 33° 45' 20" North latitude. This region is limited with the Dalab River from the south, Manesht Mountains from the east, Bankul Mountains from the north and Sharah Zool Mountains from the west (Fig. 1). The altitude in this region varies from 320 m in the north to 2650 m in the west. According to available data from the nearest climatic station to the Dalab woodlands [16], the mean annual precipitation is 560.75 mm, the mean maximum annual

temperature of the warmest month is 22° C (in July), the mean minimum annual temperature of the coldest month is 6.3 ° C (in January) and the average relative humidity of the region is 47%. The greatest number of frost days (14 days) is measured in January. The plant samples were collected by walking in June 2012. They were identified using available literature [17-22] and deposited into the herbarium of the University of Ilam (Faculty of Agriculture). The vascular flora of the region was recorded in 696 relives based on the Braun-Blanquet approach [23]. The life forms were recognized on the basis of the Raunkiaer's classification. The endemic species were determined according to Red data book of Iran [24, 25]. The phytocarya distribution of plants followed Zohary, Takhtajan and Leonard [26, 27]. The floristic list of the region is presented in Table 1. The abbreviations used in the text and the floristic list are as follows: Th: therophyte, Ch: chamaephyte, Ph: phanerophyte, Cr: cryptophyte, IT: Irano-Turanian, ES: Euro-Siberian, SS: Saharo-Sindian, Med: Mediterranean, Cosm: cosmopolitan, Endm: endemic.

3. Results and discussion

3.1. Flora

In the present survey a total of 224 species belonging to 46 families and 156 genera have been identified. Asteraceae (17 genera/29 species) is the most common angiosperm family in the region, followed by Fabaceae (8 genera/23 species), Poaceae (8 genera/22 species), Apiaceae (genera 10/18 species), Boraginaceae (6 genera/15 species), Laminaceae (8 genera /12 species), Rosaceae (4 genera/7 species), Brassicaceae (genera 6/6 species) and Liliacaea (5 genera/6 species) (Fig. 2). This shows that the representatives of Astraceae are adapted to the semiarid conditions and based on the previous studies great diversity among species of some families such as Astraceae is accompanied by

destruction of the area [28, 29]. There are 120 genera with 1 species, 23 genera with 2 species, 7 genera with 3 species and some individual genera with 4, 5, 6, 9 and 13 species. *Astragalus* (with 13 species) is the largest genus in the Dalab Woodlands then *Centaurea* (9), *Onosma* (6), *Bromus* (5) and *Amygdalus* (3) are in the next order.

3.2. Life forms

Life-form categories were determined on the basis of the Raunkiaer's classification [30]. The life form spectrum of plant species is as follows: hemicryptophytes 36.6 %, therophytes 33 %, cryptophytes 13.8 %, chamaephytes 8.9 % and phanerophytes 7.6 %. (Fig. 3).

Hemicryptophytes were the dominant life form in this area (36.6 %) followed by therophytes (33 %). The most dominant hemicryptophytes belong to the families Astraceae (14 species), Fabaceae (7 species), Boraginaceae (6 species), Laminaceae (6 species) and Poaceae (5 species). Therophytes are the second dominant life forms. The helophyte species mainly belong to family Astraceae (10 species), Poaceae (7 species) and Fabaceae (5 species).

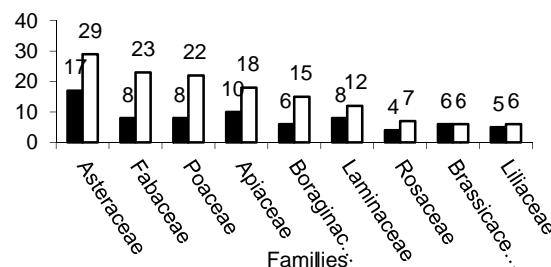

Fig. 2. The number of genera (■) and species (□) in each family

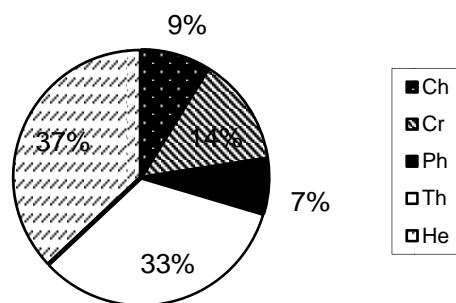

Fig. 3. The proportion of the life forms of species in Dalab Woodlands

Since the life form classification is essentially based on plant reaction to extremes of climate, it clearly reflects the adaptation of plant to environmental factors, especially climatic condition [30]. According to Mobayen, [31] the frequency of two life forms (hemicryptophytes and therophytes)

indicates the effect of the two types of Mediterranean and cold temperate climates. Hemicryptophytic species are adapted to the conditions of a particular area and develop different ways to survive, especially for reserving water, using ground water, reducing their water need by losing their leaves, reduction of vegetative growth [32] and producing their vegetative parts underground during difficult conditions. Therophytes are resistant to low rainfall and continuous drought. They finish their life cycle in a short time [33] and spend vegetative period in the form of seed [34]. According to Naqinezhad et al. (2010) [35] the presence of therophytes as second dominant life forms of the region can be partly explained by the seasonal character of water supply that supports the annual plants.

Most of the cryptophytes of the region belong to Liliaceae (7 species), Apiaceae (4), Poaceae and Geraniaceae (3 species) and Araceae (2 species) families. The chamaephytes in the region mostly belong to Fabaceae (7 species) and Plumbaginaceae (2 species) families, while most of the phanerophyte species of the region belong to Rosaceae (7 species). The low percentage of cryptophytes (being less tolerant with heat stress and drought), chamaephytes and phanerophytes indicate that these plants are not adapted to the existing climate and edaphic conditions. According to Asri, each plant species has its specific ecological area with a known tolerance to life conditions of area, and the geographical distribution of plant species depends on the life conditions of the particular area and adaptation of the plants to the site conditions [34].

3.3. Phytogeography

The phytogeographical elements include Irano-Turanian (68.7 %), Irano-Turanian/Euro-Siberian (12.9 %), Irano-Turanian/Mediterranean (6.5 %), Irano-Turanian/Euro-Siberian/Saharo-Sindian (2.2 %), Irano-Turanian/Saharo-Sindian (2.2 %), Irano-Turanian/Euro-Siberian/Mediterranean (2.2 %), Euro-Siberian/Mediterranean, Irano-Turanian/Saharo-Sindian/Mediterranean (1.3 %) and cosmopolitan (2.7 %) (Fig. 4). The phytocorya distribution of plants reflects the climate conditions. Dalab Woodlands with 68.7 % Irano-Turanian species belong to the Irano-Touranian region, characterized by low rainfall and a long dry season. This result is identical to that of Khan-Gormaz protected area in Hamedan province [32]. Irano-Turanian species of this region mostly belong to Fabaceae (18 species), Astraceae (15 species) and Poaceae (10 species) families. Examples of Irano-Turanian species are *Astragalus abnormalis*, *Centaurea irritans* and *Bromus erectus*. Most Irano-Turanian/Euro-Siberian species belong to Asteraceae (3 species), Laminaceae (3 species), Boraginaceae, Poaceae, Caryophyllaceae, and Rosaceae (each with 2 species) families. Some examples of Irano-Turanian/Euro-Siberian species are *Helianthemum salicifolium*, *Mentha longifolia*, *Heliotropium europaeum*, *Bromus tectorum*, *Minuartia meyeri* and *Cerasus microcarpa*.

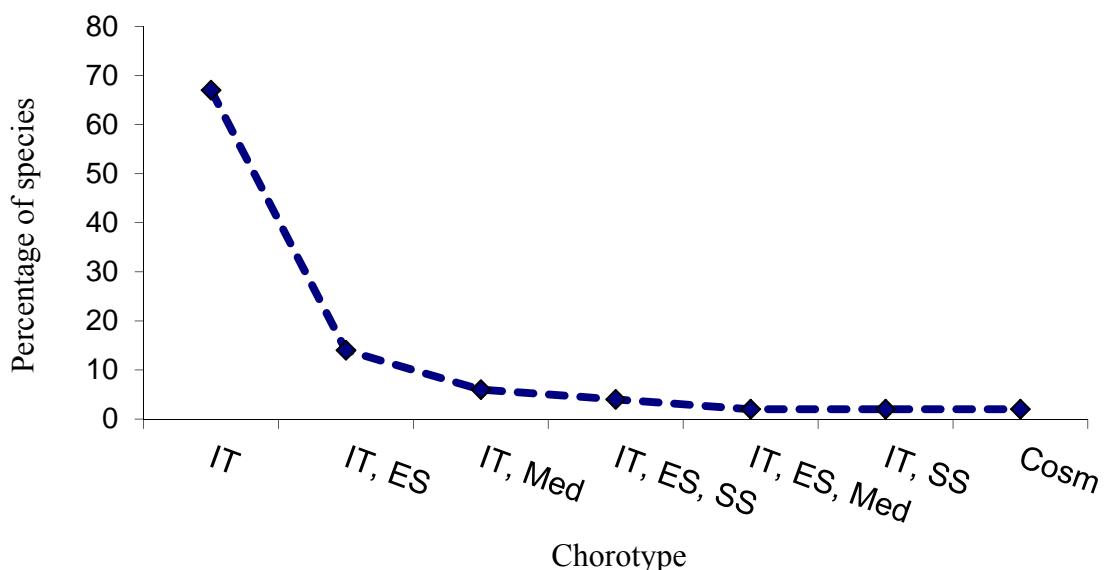

Fig 4. The percentage of phytocorya of species in Dalab Woodlands

3.4. Iranian endemics of the regions

The Zagros Mountains are one of the four main centers of endemism [24] which are characterized by a very autochthonous rich flora with high number of endemic species [36]. In total, 50 endemic species (Table 1) were identified in Dalab Woodlands region, which constitute the most valuable floristic elements of this region. Most of the endemic species of the region belong to Fabaceae (8 species) family followed by Astrarceae (4), Boraginaceae, Laminaceae, Apiaceae (3 species in each), Rosaceae and Scrophulariaceae (2 species in each) are the next. Some of the identified genera contain a relatively high proportion of endemic species. The highest proportion of

endemic species belong to *Astragalus* (with 6 species) followed by *Amygdalus* (2), *Centaurea* (2), *Cousinia* (2), *Onosoma* (2) genera. Among the endemic species, six rare species, including: *Alrawia bellii*, *Arum giganteum*, *Cousinia cylindracea*, *Echinops kotschy*, *Thymbra spicata* and *Zeugandria iranica* were also identified (Table 1). The result of the present floristic study revealed that the vascular plant flora in the Dalab Woodlands is rich in species and contains numerous endemic and rare species. However, most of the endemic and rare species are severely threatened by human disturbances. Therefore, conservation and protection management policies have to be applied to the Dalab Woodlands vegetation.
